

Distributed Software Systems

Distributed Systems Course – A.Y. 2025/2026

Enrico Ferraiolo and Daniele Romanella

Università di Bologna - DISI

A.A. 2025/2026

Part I – Daniele Romanella

- 1 Concept and Motivation
- 2 Architecture Overview
- 3 Hub Server Design
- 4 Gossip Protocol
- 5 Failure Detection
- 6 Room Lifecycle
- 7 Matchmaking
- 8 Deployment and CI/CD
- 9 Hub Testing

Part II – Enrico Ferraiolo

- 10 Room Server Design
- 11 Game Engine
- 12 Protocol and Networking
- 13 Game Loop
- 14 Fault Tolerance
- 15 Room Testing
- 16 Integration and E2E Testing
- 17 Future Works
- 18 Conclusions

What is it?

A **distributed, real-time** game playable from any terminal via CLI, inspired by **Bomberman** game.

Key properties:

- Ephemeral state – no persistent DB
- Single user role: **Player**
- Up to 4 players per match
- ASCII-rendered game board

Why distributed?

- Geographically distributed players
- Scalability via horizontal scaling
- Fault isolation between matches
- Decoupled matchmaking from gameplay

Architecture Overview – Two-Tier Design

Hub Server (AP): matchmaking, peer coordination, gossip protocol

Room Server (CP): authoritative game state, deterministic tick loop

CAP Theorem – Design Choices

Hub = AP

- Always responds to clients
- Eventual consistency via gossip
- Temporary inconsistency is tolerable

Room = CP

- Single source of truth
- Deterministic state evolution
- Disconnected clients are excluded

Hubs

Hub Server – Role and Responsibilities

Entry point for the distributed system:

- **Peer discovery** – manual or Kubernetes-based
- **Gossip protocol** – UDP + Protobuf, fanout-bounded
- **Failure detection** – two-phase timeout (suspect → dead)
- **Room management** – local pool (local development) or K8s dynamic provisioning
- **Matchmaking API** – HTTP via FastAPI
- **Room health monitoring** – periodic HTTP checks

Threading Model

- Main: Uvicorn/FastAPI
- Listener: UDP receive loop
- FailureDetector: periodic checks
- PeerDiscovery: peer count monitor
- RoomHealthMonitor: HTTP probes

All threads share HubState via RLock.

Hub Server – Domain Entities

HubState: thread-safe aggregate root (RLock) holding the local cluster view.

GossipMessage: Protobuf envelope with nonce, origin, forwarded_by, timestamp, event payload.

Two event categories:

Peer lifecycle:

- PEER_JOIN – hub announces itself
- PEER_LEAVE – graceful shutdown
- PEER_ALIVE – liveness declaration
- PEER_SUSPICIOUS – suspicion broadcast
- PEER_DEAD – death declaration

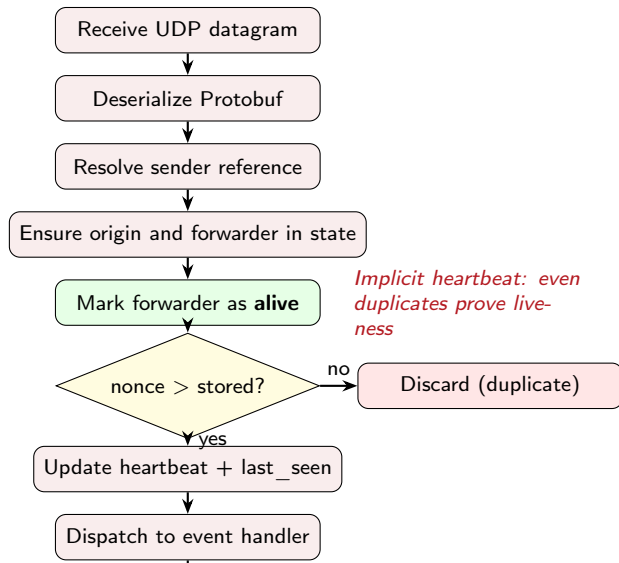

Room lifecycle:

- ROOM_ACTIVATED
- ROOM_PLAYER_JOINED
- ROOM_STARTED
- ROOM_CLOSED

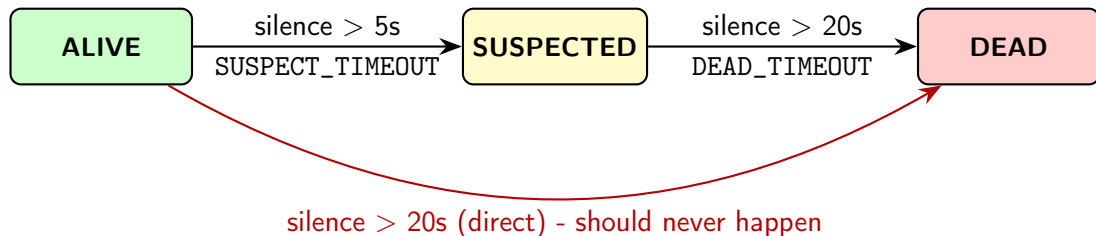

Key design choices:

- **UDP** – fire-and-forget, small datagrams
- **Protobuf** – compact binary encoding
- **Fanout-bounded** – forward to at most $F = 4$ random alive peers
- **Nonce-based dedup** – monotonic counter per origin
- **Implicit heartbeating** – any message updates last_seen

Gossip Message Processing Pipeline

Failure Detection – Two-Phase Timeout

Why two phases?

- Avoids premature removal
- Transient delays → suspicion (reversible)
- Gives suspected peer time to respond

Resurrection:

- Dead peer can rejoin automatically
- `execute_heartbeat_check` resets status
- No manual intervention needed

Room Lifecycle State Machine (Hub POV)

Room Management

- **Local mode:** fixed pool, rooms recycled on close
- **K8s mode:** dynamic pod + NodePort creation via Kubernetes API, with recovery on hub restart

Matchmaking Flow

Hub Server: StatefulSet

- 16 replicas, parallel pod management
- Stable hostnames: hub-0, hub-1, ...
- Headless service for DNS peer discovery
- Liveness + readiness probes
- Non-root, capabilities dropped

Room Server: dynamic pods

- Created on-demand by K8sRoomManager
- NodePort services for game traffic
- Labels: app=room, owner-hub
- Recovered on hub restart

Production Network Topology

Split infrastructure due to resource constraints:

- VPS terminates TLS (Let's Encrypt), reverse-proxies to K8s
- ZeroTier provides secure L2 tunnel without public IP exposure
- iptables NAT forwards game port range to MicroK8s node

CI/CD Pipeline

- GitHub Actions: CI on every push/PR, CD on main after CI passes
- Self-hosted runner co-located with the MicroK8s cluster
- E2E test runs a scripted game scenario post-deployment
- In a real scenario E2E are executed in test environment. A second deployment should be executed in production environment iff E2E passes too.

Strategy:

- 1-to-1 correspondence: class → test file
- Mock infrastructure at the boundary (UDP, K8s, HTTP)
- Focus on **observable behavior**, not call counts

Coverage areas:

- Hostname parsing and initialization
- Gossip pipeline: dedup, dispatch, forwarding
- Peer lifecycle handlers
- Failure detection state machine
- Room lifecycle and matchmaking
- Room health monitoring
- Input validation and edge cases

Rooms

Room Server – Role and Architecture

Authoritative game server for a single match:

- Runs deterministic **tick-based game loop**
- Receives player inputs via TCP + Protobuf
- Broadcasts state snapshot every tick
- Single source of truth (CP-oriented)
- Handles up to 4 concurrent clients

Two network interfaces:

- **TCP :5000** – game socket
- **HTTP :8080** – management API

Game Engine – Entities and Rules

Domain Entities:

- **GameEngine**: aggregate root – grid, players, bombs
- **Player**: ID, position, alive/dead status
- **Bomb**: position, owner, timer, blast range

Game Rules:

- Movement: collision detection vs. walls and grid bounds
- Bombs: 1 per player, timer decrements each tick
- Explosion: 4 cardinal directions, stopped by walls

State Machine

Countdown: requires ≥ 2 players. Duration decreases as more players join. Auto-starts at 4 players.

Why TCP?

- Guarantees packet ordering
- Reliability for game commands
- No lost bomb placements

Message types:

Client → Server:

- JoinRequest (player_id)
- Action
(MOVE_UP/DOWN/LEFT/RIGHT,
PLACE_BOMB, QUIT)

Server → Client:

- ServerResponse (accept/reject)
- GameStateSnapshot (ASCII grid,
is_game_over, message)
- SERVER_RESET notification

Game Loop – Tick-Based Processing

Single-Writer principle: only the GameLoop thread mutates the GameEngine.

Partial failure: if broadcast to one client fails, others still receive the snapshot.

Fault Tolerance – Checkpointing and Recovery

Local Checkpointing:

- GameEngine serialized to .pk1 file
- Every AUTOSAVE_INTERVAL ticks (5)
- No network replication overhead
- Best-effort recovery mechanism

Recovery Flow:

- 1 Server restarts, finds .pk1 file
- 2 Check timestamp: if $< 30s$ old $\rightarrow$ load
- 3 Distinguish alive vs. dead players
- 4 Set reconnection deadline
- 5 Wait for disconnected players to rejoin
- 6 If timeout expires $\rightarrow$ fresh restart

Client Disconnection:

- Error
- Player marked dead in engine
- Match continues for remaining players

Cleanup

Completed games delete save files to prevent ghost resurrection.

Coverage areas:

- Server init and crash recovery
- Lifecycle and threading model
- Game loop timing and autosave
- Client connection management
- State broadcasting (partial failures)
- Protocol translation layer
- Hub integration notifications
- Game engine and collision
- Win conditions and state machine
- Persistence and corruption handling
- Network framing protocol
- Reconnection logic
- Cross-platform input handling

Hub Server:

- Real UDP gossip between two hubs
- HTTP API endpoints (matchmaking, lifecycle)
- LocalRoomManager full lifecycle
- K8sRoomManager (mocked K8s API)
- FailureDetector with real HubState
- Gossip deduplication end-to-end
- Matchmaking flow with room activation

Room Server:

- Client-server protocol over real sockets
- Game loop via Protobuf actions
- Persistence and recovery flow
- Concurrency: multiple clients, state consistency

End-to-End Testing

- Runs in CD pipeline after deployment (300s stabilization period)
- Tests full stack: client → hub matchmaking → room → gameplay → game over
- Failure flags the deployment as broken

Demo

Hub Server:

- Eager push / lazy pull gossip for better reliability
- HMAC-based gossip authentication
- Weighted room assignment (fill level, proximity)
- Graceful hub scaling (dynamic EXPECTED_HUB_COUNT)
- Prometheus metrics for gossip layer

Room Server:

- Spectator mode
- Persistent game history (SQLite)
- Dynamic/procedural map generation

General:

- End-to-end encryption (mTLS)
- Session token-based reconnection
- Cross-region deployment with region-aware matchmaking

What we built

A **coherent distributed system** that balances availability (Hub, AP) with strong consistency (Room, CP) at different layers, each with its own CAP trade-off.

Strengths:

- Robust gossip protocol with failure detection and resurrection
- Deterministic authoritative game engine
- Production-grade K8s deployment with CI/CD
- Comprehensive testing: unit, integration, E2E

Known limitations:

- No gossip ACK mechanism (fire-and-forget)
- No authentication or encryption
- Minimal client UI (ASCII terminal)
- No persistent game history

Thank you
